1) Create a database model (JSON) in which the table is going to be stored. All of the above information has to be stored within that model.

-

2) How would you update the information of a candy parameter in that system? What do you need from the user and which mongodb CRUD operation would you use?

To update a candy parameter in that system you need the `_id` of that item. If you want to update a specific data, we need the id of that data.

You can use `updateOne()` or `updateMany()`. I have used `findOneAndUpdate()`.

3) Sometimes the lab team will delete one of the cells if it is not necessary how would you delete the cell? Which information would you need from the user and which mongodb CRUD operation would you use?

To delete cells again you need specific `_id` for that data. You can use `deleteOne()` or `deleteMany()`. I have used `deleteOne()`.
